- A1.3.2 Postquestionnaire A15
- A1.3.3 Presidential candidates in 2020 A18
- A1.4 Scales A19
 - A1.4.1 Cognitive Reflection Test (CRT) A19
 - A1.4.2 Psychological Reactance A20
 - A1.4.3 Social and Economic Conservatism Scale (SECS) A21
 - A1.4.4 Social value orientatioation (SVO) A21
 - A1.4.5 Behavioral Intentions A24
 - A1.4.6 Creating a dataframe with all variables A25

II Main analyses A26

A2 ANOVA and linear models A26

- A2.1 Prepare data for ANOVA and regressions A26
- A2.2 ANOVA models A29
- A2.3 Bar diagram A32
- A2.4 Robustness check regarding ANOVA and previously established predictors A32
- A2.5 Robustness check regarding demographic variables A38
 - A2.5.1 Demographic differences between voter samples A38
 - A2.5.2 Addressing potential confounds A40
 - A2.5.3 Addressing binarized gender identity as a confound A47

A3 Manipulation check for the framing factor A49

- A3.1 Perceived connection to the pandemic A49
- A3.2 ANOVA after filtering participants based on perceived connection to the pandemic A52

A4 Series of regression models A54

- A4.1 The basic regression model A54
- A4.2 Adding established covariates A55
 - A4.2.1 Differences between voter groups regarding covariates A55
 - A4.2.2 Adding SVO, CRT, and risk-taking A63
 - A4.2.3 Testing interactions with the framing factor A64
 - A4.2.4 Testing interactions with framing and intervention factor A66
- A4.3 Inter-correlations of conservatism variables A68
- A4.4 Adding a single conservatism measure A71
 - A4.4.1 Adding Trump preference as predictor A71
 - A4.4.2 Adding conservatism as predictor A72
 - A4.4.3 Adding SECS as predictor A74
 - A4.4.4 Probing for interactions A76
- A4.5 Adding pairs of conservatism measures A80
 - A4.5.1 Adding Trump preference and conservatism as predictors A80
 - A4.5.2 Adding Trump preference and SECS as predictors A81
 - A4.5.3 Adding conservatism and SECS as predictors A83

A4.5.4	Testing potential interactions	A85
A4.5.5	Robustness check: adding the sample factor	A90
A4.6	Visualization of interaction components	A93
A4.7	Adding perceived connection between game and pandemic	A95
A4.7.1	Adding the binary connection variable	A95
A4.7.2	Testing for an interaction with the framing factor	A97
A4.7.3	Testing for an interactions with both framing and intervention factor	A99
A4.7.4	Testing for an interaction with the intervention factor	A101
A4.7.5	Interpretation problems for the connection variable	A104
A4.7.6	Visualizing the interaction component	A107
A4.7.7	Condition-specific models	A107
A5	Game behavior as predictor of pandemic behavioral intentions	A113
A5.1	Pandemic behavioral intention measures	A113
A5.2	Sequence of models	A114
A5.3	Results for facial coverings	A115
A5.3.1	Step 1	A115
A5.3.2	Step 2	A116
A5.3.3	Step 3	A117
A5.3.4	Step 4	A119
A5.3.5	Step 5	A120
A5.4	Results for physical distancing	A123
A5.4.1	Step 1	A123
A5.4.2	Step 2	A124
A5.4.3	Step 3	A125
A5.4.4	Step 4	A127
A5.4.5	Step 5	A128
A5.5	Results for hand hygiene	A131
A5.5.1	Step 1	A131
A5.5.2	Step 2	A132
A5.5.3	Step 3	A133
A5.5.4	Step 4	A135
A5.5.5	Step 5	A137
A5.6	Results for movement restriction	A139
A5.6.1	Step 1	A139
A5.6.2	Step 2	A140
A5.6.3	Step 3	A141
A5.6.4	Step 4	A143
A5.6.5	Step 5	A145
A5.7	Most important predictors	A147
A5.8	Differences between conditions	A148
A6	Results for behavioral types	A149
A6.1	Four behavioral types	A149

A6.2	Distribution of types across conditions	A151
A6.3	Covariates and behavioral patterns	A154
A6.3.1	ANOVAs	A154
A6.3.2	Decision pattern and general risk preference	A155
A6.3.3	Decision pattern and social value orientation	A156
A6.3.4	Decision pattern and CRT	A158
A7	Postquestionnaire: Game motivation and estimates	A160
A7.1	Motivation for game behavior	A160
A7.1.1	Questions	A160
A7.1.2	Data frame preparation and subgroup definition	A161
A7.1.3	Correlation matrix and regression model across all conditions	A162
A7.1.4	Correlation matrix and regression model in the control condi- tion (neutral framing/no intervention)	A165
A7.1.5	Correlation matrix and regression model in the neutral fram- ing/intervention condition	A168
A7.1.6	Correlation matrix and regression model in the pandemic fram- ing/no intervention condition	A171
A7.1.7	Correlation matrix in the pandemic framing/intervention con- dition	A174
A7.1.8	Summary across conditions	A177
A7.2	Specific motivation for game behavior in the intervention conditions	A177
A7.2.1	Questions	A177
A7.2.2	Data preparation	A177
A7.2.3	Inter-correlation of intervention-specific items: Both frames	A179
A7.2.4	Inter-correlation of intervention-specific items: Neutral frame	A181
A7.2.5	Inter-correlation of intervention-specific items: Pandemic frame	A183
A7.2.6	Regression model for all postquestionnaire items: Intervention group with neutral frame	A185
A7.2.7	Regression model for all postquestionnaire item: Intervention group with pandemic frame	A187
A7.2.8	Summary	A189
A7.3	Estimated behavior	A189
A7.3.1	Data preparation	A189
A7.3.2	Lineplot	A190
A7.3.3	Comparison between estimates and true values	A190
A7.4	Self-other discrepancy in risk estimates	A192
A7.4.1	Data preparation	A192
A7.4.2	Comparison of groups	A194
III	Exploratory Analyses	A196
A8	Relationship between political variables and other predictors	A196
A8.1	Differences in predictor variables between voter groups	A196

A8.1.1	Data preparation	A196
A8.1.2	Violin plots	A197
A8.1.3	T-tests	A200
A8.2	Correlations of predictor variables and political variables	A201
A8.2.1	Custom correlation function and data preparation	A201
A9	Correlations with exploratory variables	A204
A9.1	Data preparation	A204
A9.2	Correlations (part 1)	A211
A9.3	Correlations (part 2)	A214

List of Figures

A1	Game scores by framing, intervention and voter type	A33
A2	Game scores by framing, intervention and voter type	A48
A3	Intercorrelation between conservatism measures	A70
A4	Visualization of the model prediction change induced by the SECS and Trump preference components of the model equation: The color of points in the scatterplots illustrates the additive change in the number of riskier choices predicted for each individual due to the conservatism components in the model (positive numbers correspond to a higher number predicted)	A95
A5	Proportion of participants connecting game and pandemic split by framing, intervention, and voter type	A106
A6	Value of the interaction components for drawn connection and the intervention factor in the model: Colors represent the value of the sum of terms in the fitted model for each participant.	A108
A7	Inter-correlation matrix of pandemic behavior measures.	A114
A8	Inter-correlation matrix of pandemic behavior measures, SVO and preference for Trump.	A148
A9	Mosaic plot of decision patterns by conditions [imported from an RStudio output.] The abbreviations used are "Tr": Trump voters, "Cl": Clinton voters, "Pd": Pandemic frame, "Nt": Neutral frame, "Norms": Norms intervention, "None": No intervention.	A153
A10	Ridge plot of risk preference distribution by decision pattern.	A156
A11	Ridge plot of the distribution of the social value orientation angle by decision pattern.	A158
A12	Mosaic plot of CRT scores by decision pattern [imported from an RStudio output.]	A160
A13	Inter-correlation matrix of postquestionnaire items, SVO, CRT, risk preference and game decisions: Entire sample.	A163
A14	Inter-correlation matrix of postquestionnaire items, SVO, CRT, risk preference and game decisions: Neutral frame without intervention.	A166
A15	Inter-correlation matrix of postquestionnaire items, SVO, CRT, risk preference and game decisions: Neutral frame with intervention.	A169

A16	Inter-correlation matrix of postquestionnaire items, SVO, CRT, risk preference and game decisions: pandemic frame without intervention.	A172
A17	Inter-correlation matrix of postquestionnaire items, SVO, CRT, risk preference and game decisions: pandemic frame with intervention.	A175
A18	Inter-correlation matrix of specific postquestionnaire items, SVO, CRT, risk preference and game decisions: Both intervention groups.	A180
A19	Inter-correlation matrix of specific postquestionnaire items, SVO, CRT, risk preference and game decisions: Intervention in neutral frame.	A182
A20	Inter-correlation matrix of specific postquestionnaire items, SVO, CRT, risk preference and game decisions: Intervention in pandemic frame.	A184
A21	Estimated proportions of participants choosing the H/no mask option in each condition bsplit by voter sample.	A191
A22	Boxplots of estimated proportions of participants ending the game in the purple/infected state in each condition split by voter sample.	A195
A23	Violin plot comparing voter groups in general risk preference	A197
A24	Violin plot comparing voter groups in cognitive reflection scores	A198
A25	Violin plot comparing voter groups in social value orientation (prosociality)	A199
A26	Violin plot comparing voter groups in psychological reactance	A199
A27	Correlation matrix for political and other predictor variables	A203
A28	Correlations between exploratory variables (in rows) and Conservatism, Trump endorsement, game behavior, and behavioral intentions (Part 1): Game behavior is correlated for the whole group and the four framing and intervention combinations separately. The backgrounds for significant correlation coefficient cells ($p < .05$) are colored in blue (positive) and orange (negative).	A213
A29	Correlations between exploratory variables (in rows) and Conservatism, Trump endorsement, game behavior, and behavioral intentions (Part 2): Game behavior is correlated for the whole group and the four framing and intervention combinations separately. The backgrounds for significant correlation coefficient cells ($p < .05$) are colored in blue (positive) and orange (negative).	A216

List of Tables

A1	Percentage of participants stating to have drawn a connection between transmission game and pandemic during the simulation, split by framing condition, intervention condition, and voter group.	A50

Part I

Data preparation

A1 Data preparation

This document was prepared in Overleaf, as an Rtex file implementing knitr. Any output is generated by R during compilation, and can thus be replicated by entering the same commands referencing the same dataset. Overleaf's R version and selection and versions of packages are not under the user's control. This section demonstrates the R version and the list of packages used for calculations and output generation. <https://cran.r-project.org/web/packages/psych/psych.pdf>

A1.1 R libraries

```
library(foreign)
library(formatR)
library(ggplot2)
#library(tidyr)
library("purrr")
library("tidyverse")

## Warning in system("timedatectl", intern = TRUE): running command
' timedatectl' had status 1
## - Attaching core tidyverse packages ----- tidyverse 2.0.0 -
## v dplyr      1.1.2      v stringr    1.5.0
## v forcats   1.0.0      v tibble     3.2.1
## v lubridate 1.9.2      v tidyr     1.3.0
## v readr     2.1.4
## - Conflicts ----- tidyverse_conflicts() -
## x dplyr::filter() masks stats::filter()
## x dplyr::lag()    masks stats::lag()
## i Use the conflicted package (<http://conflicted.r-lib.org/>) to force
all conflicts to become errors

library("psych", verbose=TRUE)

##
## Attaching package: 'psych'
##
## The following objects are masked from 'package:ggplot2':
##
##   %+%, alpha

library("rmarkdown", verbose=TRUE)
library("viridis")
```

```
## Loading required package: viridisLite

library(viridisLite)
#library("GGally") ## not in Overleaf
library(afex)

## Loading required package: lme4
## Loading required package: Matrix
##
## Attaching package: 'Matrix'
##
## The following objects are masked from 'package:tidyr':
##
##   expand, pack, unpack
##
## *****
## Welcome to afex. For support visit: http://afex.singmann.science/
## - Functions for ANOVAs: aov_car(), aov_ez(), and aov_4()
## - Methods for calculating p-values with mixed(): 'S', 'KR', 'LRT', and
##   'PB'
## - 'afex_aov' and 'mixed' objects can be passed to emmeans() for
##   follow-up tests
## - Get and set global package options with: afex_options()
## - Set sum-to-zero contrasts globally: set_sum_contrasts()
## - For example analyses see: browseVignettes("afex")
## *****
##
## Attaching package: 'afex'

A1.1.1 *ggthemes*

Parts of The library *ggthemes* were inserted manually in this document by copying the code from <https://github.com/jrnold/ggthemes> for "economist" and "theme_foundation" on 06.09.2023 in version v4.2.4. The code is not echoed into this document, but it is executed at this point.

```
## NULL
## [1] ".data"
```

A1.1.2 *ggmosaic*

Due to complex dependencies of the package *ggmosaic*, it was not possible to include this package in Overleaf. Two figures were created using this package. For these figures, we give the source code (generating an expected error during compilation) and add the figure exported from RStudio as a png-file.

A1.2 Load dataset

```
data=read.spss("PartisanDifferencesDeidentifiedMay24.sav")
saveData<-data
df=data.frame(data)
```

A1.3 Calculate variables

The following parts are similar to the calculations in the Scales and Variables document. Diagnostic output has been suppressed in this version, though. See the other document (SV) for scale consistency, scale distributions, and item inter-correlation information.

A1.3.1 *Game behavior*

```

scaleVarsTG <- c("TG_R01Choice", "TG_R02Choice", "TG_R03Choice",
                "TG_R04Choice", "TG_R05Choice", "TG_R06Choice",
                "TG_R07Choice", "TG_R08Choice", "TG_R09Choice",
                "TG_R10Choice", "TG_R11Choice", "TG_R12Choice",
                "TG_R13Choice", "TG_R14Choice", "TG_R15Choice",
                "TG_R16Choice", "TG_R17Choice", "TG_R18Choice",
                "TG_R19Choice", "TG_R20Choice", "TG_R21Choice",
                "TG_R22Choice", "TG_R23Choice", "TG_R24Choice",
                "TG_R25Choice"
)

scaleFrameTG <- df[scaleVarsTG]
remove(scaleVarsTG)

scaleFrameTG <- scaleFrameTG %>%
  dplyr::rename(
    R01=TG_R01Choice,R02=TG_R02Choice,R03=TG_R03Choice,
    R04=TG_R04Choice,R05=TG_R05Choice,R06=TG_R06Choice,
    R07=TG_R07Choice,R08=TG_R08Choice,R09=TG_R09Choice,

A2.2 ANOVA models

The three-factorial ANOVA model with the factors framing, intervention, and voter type mirrors the structure of the experiment. The ANOVA shows clear main effects for all three factors with a two-way interaction between framing and intervention. Coefficients and the bar diagram in Figure A2 below demonstrate that the effect of the intervention is smaller in the mask version of the game than in the color version, while the direction of the effect remains the same.

```

```

A2.4 Robustness check regarding ANOVA and previously established predictors

In our previous study, we found correlations of game scores and behavioral types with three covariates: social values orientation (Murphy et al., 2011), a CRT measure

Figure A1
Game scores by framing, intervention and voter type

(Frederick, 2005; Woike, 2019), and a general risk item measure (Dohmen et al., 2011).

Two ANCOVA-models were estimated to test the robustness of the results when these three predictors were added as covariates.

```

```

Results of the ANOVA and ANCOVA are generally comparable. Again, social value orientation and risk taking but not the CRT are significant predictors. The main effect of voter sample is attenuated in the ANCOVA model.

The comparison between the two groups demonstrates a higher social value orientation angle (indicating more prosocial choices), a higher cognitive reflection score, and a lower degree of general risk preference in the Clinton voter sample.

```

The attenuation might thus be either due to the explanatory power of the three predictors or due to a spurious correlation with other differences between the two voter samples. To explore the relationship further, we estimated a series of regression model without the sample factor (see Section A4).

A2.5 Robustness check regarding demographic variables

A2.5.1 Demographic differences between voter samples

Republican and Democratic voters differ in demographic variables, and this is also true for our samples. We have collected information on age, gender, and education.

```

```

There are differences in gender distribution and age, and smaller discrepancies regarding attained education levels.

A2.5.2 Addressing potential confounds

Our main analysis included the voter factor that is correlated with demographic variables as seen above. Our main model did not include demographic variables, as we had not observed a relationship between game decisions and age and gender in our previous study Woike et al., 2022. In this context, it is relevant to stress that we measure risk taking in the context of a social dilemma, not risk taking per se. We originally had no research hypotheses regarding gender and age, but some comments received on an earlier version of the manuscript motivated us to address possible concerns regarding these variables. To exclude the possibility that these variables could explain the observed effects, we present

additional models here that add these variables to the analysis.

In the first model, we add gender and age.

```

Education is a significant predictor of game behavior, but none of the previously

observed effects changes to a substantial degree. Isolating the education factor, the pattern of differences between subgroups is visualized below.

```
ggplot(data=modelTestFrame, aes(x=education, y=RiskyChoices)) +
  stat_summary(geom="bar", fun=mean, position="dodge")+
  stat_summary(fun.data = mean_se, geom = "errorbar",
    position=position_dodge(width=0.9), width=0.2)+
  theme_economist()+
  scale_color_manual(values=c("#661100", "#6699CC"))+
  scale_fill_manual(values=c("#661100", "#6699CC"))+
  scale_linetype_manual(values=c("solid", "dotted"))+
  labs(title='Average number of risky choices',
    subtitle="Split by attained education level")+
  theme(axis.title.y =element_text(vjust=3) ,
    axis.title.x =element_text(vjust=-2))+
  labs(y="count")
```

The larger deviations from the overall mean can be attributed to three groups that have the lowest number of members (about 60 participants in total). Splitting the analysis further by voting group again reveals no indication that education can help to explain the obtained findings:

```
ggplot(data=modelTestFrame, aes(x=education, y=RiskyChoices, fill=facSample)) +  
  stat_summary(geom="bar", fun=mean, position="dodge")+  
  stat_summary(fun.data = mean_se, geom = "errorbar",  
              position=position_dodge(width=0.9), width=0.2)+  
  theme_economist()+  
  scale_color_manual(values=c("#661100", "#6699CC"))+  
  scale_fill_manual(values=c("#661100", "#6699CC"))+
```

```

scale_linetype_manual(values=c("solid","dotted"))+
labs(title='Average number of risky choices',
      subtitle="Split by attained education level and voter group")+
theme(axis.title.y =element_text(vjust=3) ,
       axis.title.x =element_text(vjust=-2))+
labs(y="count")+
facet_wrap(~facSample)

```

With the exception of a single participant in the "some high school" category, the averages in all educational categories are lower (within the educational category) in the Clinton voter sample than in the Trump sample.

A2.5.3 Addressing binarized gender identity as a confound

Many analyses of risk-taking use binarized gender identities as a predictor. Without conceding the appropriateness of this simplified categorization Godman, 2018, we want to demonstrate that our results do not depend on the additional degrees of freedom in our gender factor. In a first step, we filter the total sample to exclude all participants not identifying as male or female, and then compare the average risk taking for male and female voters between voter samples.

```
modelFilteredTestFrame = subset(modelTestFrame, (gender == 'Male') |(gender == 'Female'))

ggplot(data=modelFilteredTestFrame, aes(x=gender, y=RiskyChoices, fill=facSample)) +
  stat_summary(geom="bar", fun=mean, position="dodge")+
  stat_summary(fun.data = mean_se, geom = "errorbar",
              position=position_dodge(width=0.9), width=0.2)+
  theme_economist()+
  scale_color_manual(values=c("#661100", "#6699CC"))+
  scale_fill_manual(values=c("#661100", "#6699CC"))+
  scale_linetype_manual(values=c("solid", "dotted"))+
  labs(title='Average number of risky choices',
       subtitle="Split by gender (male/female) and voter group")+
  theme(axis.title.y =element_text(vjust=3) ,
        axis.title.x =element_text(vjust=-2))+
  labs(y="count")+
  facet_wrap(~facSample)
```

In each gender category, Clinton voters take less risk in the game than Trump voters, with Clinton voters identifying as male taking less risk than Trump voters identifying as female. Using the simplified gender variable in the ANOVA model tested earlier results in the same pattern of findings as before.

```
modelFilteredTestFrame = subset(modelTestFrame, (gender == 'Male') |(gender == 'Female'))

options(contrasts = c("contr.sum", "contr.poly"))
lmANOVAdem2<-lm(RiskyChoices~facFraming*facInterv*facSample+gender+age+education,
               data = modelFilteredTestFrame)

modANOVAdem2<-Anova(lmANOVAdem2, type="III")

```

In summary, the observed pattern of results cannot be explained by differences in demographic factors. As this series of models was computed after the completion of the manuscript, we opted to place it into the supplementary material and not into the main manuscript.

A3 Manipulation check for the framing factor

A3.1 Perceived connection to the pandemic

Here, we consider the threat posed by the ubiquitous nature of the pandemic in media reporting and also in online research at the time of the study, which might have pre-disposed participants to interpret the game as related to the pandemic irrespective of

Table A1

Percentage of participants stating to have drawn a connection between transmission game and pandemic during the simulation, split by framing condition, intervention condition, and voter group.

Framing	Intervention	Voter group	
		Clinton	Trump
Colors	no	15.9	12.9
	yes	14.8	15.2
Masks	no	98.1	90.5
	yes	100.0	91.1

framing condition. In the post-questionnaire, we asked participants irrespective of condition whether they had drawn a connection between the transmission game and the pandemic before being prompted to think about it by the question (see Tab. A1). In theory, framing should impact these perceptions, but not the presence of an intervention or the specific voter group. This is indeed what the results show with the vast majority (>90% in all conditions) seeing the connection in the pandemic framing, and the minority of participants drawing this connection in neutrally framed conditions (less than a sixth of participants in all cases). As a robustness check, we filtered out participants that had either drawn a connection with the pandemic in the neutrally framed conditions or not drawn a connection in the pandemic-framed conditions. The pattern of results found for the ANOVA in the main manuscript remained unchanged.

A3.2 ANOVA after filtering participants based on perceived connection to the pandemic

We included a manipulation check for the framing factor, in which we asked participants whether they had drawn a connection between the scenario and the pandemic. Given the prevalence of studies addressing pandemic-related topics at the time of data collection, there is a possible concern that the neutral scenario was not considered to be neutral. In the following analysis we excluded participants who stated to have seen a connection during the game in the neutrally-framed conditions (and also those participants who did not see the connection in the pandemic-framed conditions).

```

##
## - One-sided CIs: upper bound fixed at [1.00].
```

A comparison of ANOVA results shows the identical qualitative pattern of results with the same significant effects as before. A direct comparison of effect sizes shows an increase for the effect size of the framing factor (as to be expected) and also a slight increase of the interaction involving the framing factor. The changes do not rise to a level of concern, and we decided to report the unfiltered analysis in the main manuscript.

A4 Series of regression models

A4.1 The basic regression model

We start with a regression model that is virtually identical to the two-factorial ANOVA model. The intercept in this model represents the mean number of risky choices in the control condition. The three dummy variables adapt to the differences between conditions. The "mask" dummy is coded 1 for every observation in the pandemic frame conditions and 0 otherwise (the mean in the condition with pandemic frame and without an intervention must correspond to the sum of intercept and mask dummy). The "injunctive" dummy is coded 1 for every observation in the injunctive norms conditions and 0 otherwise (the mean in the condition with intervention and without pandemic frame corresponds to the sum of intercept and injunctive dummy). The final dummy "MasksInj" is coded 1 for observations in the condition with both pandemic frame and injunctive norms intervention (the mean in this condition corresponds to the sum of the intercept and all three dummy values).

```
lm0<-lm(RiskyChoices~dummyMasks+dummyInjunctive+dummyMasksInj,
        data = modelFrame)
mod0<-Anova(lm0, type="III")
print(mod0)

## Anova Table (Type III tests)
##
## Response: RiskyChoices
##              Sum Sq Df F value    Pr(>F)
## (Intercept)  28037   1 585.489 < 2.2e-16 ***
## dummyMasks    7761   1 162.073 < 2.2e-16 ***
## dummyInjunctive 3649   1  76.210 < 2.2e-16 ***
## dummyMasksInj  1275   1  26.632 3.094e-07 ***
## Residuals    39028 815
```

```
## ---
## Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

lm0$coefficients

##      (Intercept)      dummyMasks dummyInjunctive  dummyMasksInj
##      11.840000      -8.724615      -5.989758      4.992021

print(eta_squared(mod0, partial = TRUE, ci=.95, verbose=FALSE))

## # Effect Size for ANOVA (Type III)
##
## Parameter          | Eta2 (partial) |          95% CI
## -----
## dummyMasks         |          0.17 | [0.13, 1.00]
## dummyInjunctive    |          0.09 | [0.06, 1.00]
## dummyMasksInj      |          0.03 | [0.01, 1.00]
##
## - One-sided CIs: upper bound fixed at [1.00].

anova(lm0, lmANOVA2)

## Analysis of Variance Table
##
## Model 1: RiskyChoices ~ dummyMasks + dummyInjunctive + dummyMasksInj
## Model 2: RiskyChoices ~ facFraming * facInterv
##   Res.Df  RSS Df Sum of Sq F Pr(>F)
## 1      815 39028
## 2      815 39028  0          0
```

The residual sum of squares is (unsurprisingly) identical to the residual sum of squares in the two-factorial ANOVA above.

A4.2 Adding established covariates

We replicate the results from the previous study for social value orientation and risk-taking. The relationship between the CRT and game behavior is further explored in the section dealing with behavioral types.

A4.2.3 Testing interactions with the framing factor

To test whether the relationship between game behavior and predictors might be condition-specific, we compare the model above (lm_1) with a model adding interactions between the framing factor and the covariates (calculated as products between condition dummy and each covariate).

```
lm1I<-lm(RiskyChoices~dummyMasks+dummyInjunctive+dummyMasksInj+

```

Again, this model does not significantly improve the model without interactions nor the model with framing interactions. Thus, we keep the three predictors as simple covariates.

A4.3 Inter-correlations of conservatism variables

Three variables potentially capture the main differences between the two voter groups. As preregistered, we explore their potential for explaining behavioral differences in the transmission game. These three variables are a simple conservatism item asking for the political position on a scale from very liberal to very conservative. A second measure captures conservatism by asking for the evaluation of multiple partisan issues. The Social and Economic Conservatism Scale (SECS) has two correlated subscales, social conservatism and economic conservatism. As a third measure, we asked for the preference for presidential candidates in 2020. The Prolific samples were selected based on voting behavior in 2016. The preference for an electoral win for Donald Trump was thus a likely candidate for capturing the differences between samples, even if some voters might have changed their preference in the mean time.

```
conservatismMatrix=data.frame(
  conservatismItem=modelFrame$conservatism,
  SECSFull=modelFrame$SECS,
  SECSEcon=modelFrame$SECSEcon,
  SECSSocial=modelFrame$SECSSoc,
  trumpPref=modelFrame$trump
```

```
)
```

An analysis of the inter-correlations between these measures shows the expected pattern of high positive correlations between measures (see Fig. A3).

```
corMatrix<-cor(conservatismMatrix,use="complete.obs")  
corrplot(corMatrix,type="lower",method="number")
```

Thus, it does not seem to be a good idea to simply add all three variables to the model. Instead, we enter variables on their own and in pairs to test whether predictions can be substantially improved.

Figure A3
Intercorrelation between conservatism measures

A4.4 Adding a single conservatism measure

A4.4.1 Adding Trump preference as predictor

```

```

Adding the single conservatism item leads to an improvement, but not a significant improvement of the model. One should note that there is a relationship between conservatism and the other predictors in the model. A model without these predictor shows a coefficient for the conservatism factor that is significantly different from zero. These relationships are explored in section A8.

```

Adding the SECS scale leads to an improvement of the model that is significant but with a smaller effect size than the electoral preference variable. In the next step, we explore interactions between the preference variable and design factors.

A4.4.4 Probing for interactions

Given the politicization of mask-wearing, we hypothesize an interaction between the effect of political preferences and the framing factor. Model *mode_{2c}* adds the product between dummy and preference variable.

```

```

The full model still shows a significant improvement over the model with a single predictor or two predictors without interactions, but not over the model with solely the framing interaction.

A4.5.5 Robustness check: adding the sample factor

To test whether the added components capture the relevant information of the voter sample factor, we add this factor to the model to see whether it can still be improved by this addition. In the first model we just add a dummy for the sample, in the second we add the full model with interactions.

```

```

Adding the interaction components in model mod_{3dF} does not significantly improve model mod_{3dS} , and all four components together do not improve the original model. Thus, the chosen variables capture the relevant information contained in the sample components.

A4.6 Visualization of interaction components

An analysis of the coefficients in the model shows an interesting difference in the direction of the SECS and the preference items between framing conditions. To visualize

this pattern, we first isolate the additive components in the linear model.

```
lm3d<-lm(RiskyChoices~dummyMasks+dummyInjunctive+dummyMasksInj+angleSVO+
  CRT+riskTaking+trump+SECS+mSkTrump+mSkSECS,
  data = modelFrame)

interactionFrame=modelFrame

interactionFrame$facFraming<-factor(interactionFrame$facFraming,
  levels =c("NEUTRAL  ", "MASKS  "))
interactionFrame$facFraming<-factor(interactionFrame$facFraming,
  labels=c("Neutral", "Masks"))

interactionFrame$facInterv<-factor(interactionFrame$facInterv,
  levels =c("NONE      ", "INJUNCTIVE  "))
interactionFrame$facInterv<-factor(interactionFrame$facInterv,
  labels=c("None", "Norms"))

interactionFrame$facSample<-factor(interactionFrame$facSample,
  levels =c("Conservatives", "Liberals"))
interactionFrame$facSample<-factor(interactionFrame$facSample,
  labels=c("Trump", "Clinton"))

interactionFrame$residualsMasks=lm3d$residuals
interactionFrame$predictionsMasks=lm3d$fitted.values

interactionFrame$InteractComp=lm3d$coefficients[8]*interactionFrame$trump+
  lm3d$coefficients[9]*interactionFrame$SECS+
  lm3d$coefficients[10]*interactionFrame$mSkTrump+
  lm3d$coefficients[11]*interactionFrame$mSkSECS
```

Figure A4 shows the value of the conservatism component (trump+SECS+mSkTrump+mSkSECS) for all combinations of the three experimental factors. For each condition, the scatterplot shows the distribution of the preference variable (for President Donald Trump) and the SECS scale with the color indicating the sum of the weighted components. In all conditions, higher values of the preference item are associated with a larger number of riskier decisions. Higher values of SECS are associated with higher numbers of H/no mask decisions in the neutral framing, but with lower numbers in the pandemic framing. The clear distributional differences between Trump and Clinton voters result in overall higher values for Trump than for Clinton voters, which recovers the differences that were observed between the samples.

```
ggplot(data=interactionFrame, aes(x=trump, y=SECS, col=InteractComp)) +
  geom_point()+geom_jitter()+facet_wrap(~facFraming~facInterv~facSample,
  ncol=4)+scale_color_viridis(option="magma")+theme_dark()
```

Figure A4

Visualization of the model prediction change induced by the SECS and Trump preference components of the model equation: The color of points in the scatterplots illustrates the additive change in the number of riskier choices predicted for each individual due to the conservatism components in the model (positive numbers correspond to a higher number predicted)

```
xlab("Trump preference")
```

A4.7 Adding perceived connection between game and pandemic

In our preregistration, we discussed a potential role for the perceived connection between game scenario and the pandemic. Participants were asked after the game whether they drew this connection before seeing the question, after reading the question or not at all. To analyze the effect of the variable we binarize this variable: Only those participants who indicated seeing the connection during the game were categorized as positive cases (as only for these participants, the insight might have influenced their game decisions). This is represented by the variable "binaryConnection".

A4.7.1 Adding the binary connection variable

```
lm4a<-lm(RiskyChoices~dummyMasks+dummyInjunctive+dummyMasksInj+angleSV0+
  CRT+riskTaking+trump+SECS+mSkTrump+mSkSECS+binaryConnection,
  data = modelFrame)
```

```

mod4a<-Anova(lm4a, type="III")
print(mod4a)

Adding this interaction significantly improves the model. An analysis of the coefficients shows that the coefficient for the intervention condition nearly cancels out the coefficient in the non-intervention condition. A closer analysis reveals problems for a simple interpretation of this coefficient.

A4.7.5 Interpretation problems for the connection variable

Comparing the previous models with *mod_{4D}*, the two-factorial interaction between intervention and framing is no longer significant in the new model. The following code calculates means for risky choices and the proportion of participants that saw a connection in all four conditions split by sample.

```
interactionFrame$binaryConnection=
  as.numeric(as.factor(interactionFrame$binaryConnection))-1

tapply(interactionFrame$RiskyChoices,
       list(as.factor(interactionFrame$binaryConnection),
            interactionFrame$facFraming, interactionFrame$facInterv,
            interactionFrame$facSample), function(x) mean(x))

## , , None, Trump
##
##      Neutral      Masks
## 0 13.76543  8.800000
## 1 11.16667  3.789474
##
## , , Norms, Trump
##
##      Neutral      Masks
## 0  6.380952  2.555556
## 1  6.733333  2.967391
##
## , , None, Clinton
##
##      Neutral      Masks
## 0 11.233333 10.500000
## 1  6.352941  1.772277
##
## , , Norms, Clinton
##
```

```
##      Neutral      Masks
## 0 5.782609      NA
## 1 2.625000  1.320388

tapply(100*interactionFrame$binaryConnection,
       list(interactionFrame$facFraming,interactionFrame$facInterv,
            interactionFrame$facSample), function(x) mean(x))

## , , Trump
##
##           None      Norms
## Neutral 12.90323 15.15152
## Masks   90.47619 91.08911
##
## , , Clinton
##
##           None      Norms
## Neutral 15.88785 14.81481
## Masks   98.05825 100.00000
```

Non-surprisingly, the proportion of drawn connections is quite high in the pandemic framing (>90%; with even higher values in Clinton voter sample) and quite low in the neutral framing (<16%). In other words, there is a high overlap between framing factor and connection variable (see also Figure A5) .

```
##modelFrame$facSample<-factor(modelFrame$facSample,
##                               levels =c("Conservatives","Liberals"))

modelFrame$facSample<-factor(modelFrame$facSample,
                              labels=c("Trump","Clinton"))

modelBarFrame <- modelFrame

##levels (modelBarFrame$facFraming) <- list ("Neutral frame"="Neutral", "Pandemic frame"="M
##levels (modelBarFrame$facIntervention) <- list ("None"="None", "Norms intervention"="Norm

modelBarFrame$facFraming<-factor(modelBarFrame$facFraming, levels =c("NEUTRAL", "MASKS
modelBarFrame$facFraming<-factor(modelBarFrame$facFraming,labels=c("Neutral frame","Pandemi

modelBarFrame$facInterv<-factor(modelBarFrame$facInterv, levels =c("NONE", "INJUN
modelBarFrame$facInterv<-factor(modelBarFrame$facInterv,labels=c("None","Norms intervention

ggplot(data=modelBarFrame, aes(x=facInterv,
```

**Figure A5**

labs(title='Proportion of participants connecting game and pandemic',
      subtitle="Split by framing, intervention and voter type")+
theme(axis.title.y =element_text(vjust=3) ,
      axis.title.x =element_text(vjust=-2))+
labs(y="Proportion connecting game and pandemic")+
labs(fill="Voter type")

```

Based on this analysis, it is unclear what is really captured in the model. Visualizing

the interaction component in the fitted model demonstrates the components impact on predictions.

A4.7.6 *Visualizing the interaction component*

```
interactionFrame$ConnectionComp=
  lm4d$coefficients[12]*interactionFrame$binaryConnection+
  lm4d$coefficients[13]*interactionFrame$injConnection

ggplot(data=interactionFrame, aes(x=binaryConnection, y=ConnectionComp,
                                  col=ConnectionComp)) +
  geom_point()+geom_jitter()+
  facet_wrap(~facFraming~facInterv~facSample,ncol=4)+
  scale_color_viridis(option="magma")+
  theme_dark()+xlab("Connection drawn")
```

Figure A6 visualizes the impact of the term *binaryConnection + injConnection* in the fitted model. There are small differences in prediction for those drawing and not drawing the connection in the normative intervention condition. There is a difference of about four choices between these two groups in the condition without intervention. It remains an open question, though, whether the predictions in the top left part and bottom left part are both warranted. Do those rejecting the seemingly obvious connection between masks inside and outside the game really make riskier choices than those who saw the connection? And is there really a relationship between seeing the connection and a lower number of riskier choices in the color condition? Based on the design of this study, it is impossible to address the question of direction of causality: There might after all even be a third variable explaining both caution in the game and likelihood to draw the connection.

A4.7.7 *Condition-specific models*

To explore the predictive usefulness of the connection variable, we fit four separate models in the four conditions of the experiment. These models obviously drop the interaction components but contain all other covariates.

```
conditionFactorFour= (as.numeric(modelFrame$facFraming)-1)*2+
  as.numeric(modelFrame$facInterv)

cond4=as.numeric(factor(conditionFactorFour, labels =c('Mskr-Inj', 'Msk-No',
                                                    'Clr-Inj', 'Clr-No')))

modelFrame$cond4=cond4

groupNoIntervNoFraming <- modelFrame[which(modelFrame$cond4==4),]
groupIntervNoFraming <- modelFrame[which(modelFrame$cond4==3),]
```

**Figure A6**

Value of the interaction components for drawn connection and the intervention factor in the model: Colors represent the value of the sum of terms in the fitted model for each participant.

```
groupNoIntervFraming <- modelFrame[which(modelFrame$cond4==2),]
groupIntervFraming <- modelFrame[which(modelFrame$cond4==1),]
```

We first split the sample into the four respective experimental groups. These analyses of course use sub-samples and suffer from a lower power to detect differences.

```
lmColControl<-lm(RiskyChoices~angleSVO+
                 CRT+riskTaking+trump+SECS+binaryConnection,
                 data = groupNoIntervNoFraming)

```

Finally, in the pandemic framing with intervention, SVO and preference for Trump were the only significant predictors.

One possible explanation for this pattern of results is that the injunctive norms condition made the connection between game and pandemic irrelevant, as the social dilemma was clearly spelled out. Risk taking became a more pronounced predictor in the intervention conditions, potentially because these conditions stressed the risk of choosing option H/no mask. The single models also confirm the usefulness of including the interactions between conservatism variables and the framing factor. This effect is consistent with the idea that

masks have become politicized.

A5 Game behavior as predictor of pandemic behavioral intentions

A5.1 Pandemic behavioral intention measures

We used four scales measuring behavioral intentions. The face covering subscale (BI-FC) was adapted from Capraro and Barcelo (2021). The three item texts were copied verbatim, the first part of the sentence has been altered. Items BI-HH2+, BI-HH3+, and BI-MR3+ were adapted from Jordan et al. (2021). The remaining items were adapted from various government guidelines and public health webpages.

The items were introduced with the sentence "In light of the coronavirus outbreak, I intend to...". Items are categorized into four subscales and measured on a scale from -50 ("Strongly disagree") to 50 ("Strongly agree").

- **BI-MR1+**: ...leave my home only for essentials.
- **BI-PD1+**: ...avoid face-to-face interactions with friends.
- **BI-PD2+**: ...engage in physical contact with no one other than those I live with.
- **BI-MR2+**: ...self-quarantine if feeling sick for a minimum of 14 days.
- **BI-HH1+**: ...wash my hands regularly for 20 seconds.
- **BI-HH2+**: ...stop shaking other people's hands.
- **BI-HH3+**: ...try my hardest to avoid touching my face.
- **BI-MR3+**: ...try to stay home whenever possible, even if I am not sick.
- **BI-PD3+**: ...remain at least 6 feet away from other people.
- **BI-FC1+**: ...wear a face covering any time I leave home.
- **BI-FC2+**: ...wear a face covering any time I am engaged in essential activities and/or work, and there is no substitute for physical distancing and staying at home.
- **BI-FC3+**: ...wear a face covering any time I'm around people outside my household.

The four subscales are intentions to 1) wear a face covering, 2) engage in physical distancing, 3) observe proper hand hygiene, and 4) restrict one's movement during the pandemic. One might note that the focus on hand hygiene was most pronounced in the beginning of the pandemic and at the time of the study, the focus had not yet fully shifted towards ventilation and aerosols.

Figure A7 shows the inter-correlation matrix between variables, showing medium to high correlations between all four scales. It still makes sense to study relationships between game behavior and each of these measures, as the game itself in the framing condition focuses on masks in particular and least on hand hygiene.

**Figure A7**

Inter-correlation matrix of pandemic behavior measures.

```
behaviorFrame=data.frame(
  Masks=modelFrame$behIntMasks,
  Distancing=modelFrame$behIntDistancing,
  HandHygiene=modelFrame$behIntHandHYgiene,
  MovementRestrictions=modelFrame$behIntMovement
)

corMatrix<-cor(behaviorFrame,use="complete.obs")
corrplot(corMatrix,type="lower",method="number")
```

A5.2 Sequence of models

To avoid finding spurious correlations between game behavior and behavioral intentions, we add other potential predictors to the model first. For each of the scales, we add the cognitive reflection test (CRT), general risk taking (riskTaking) and the social value orientation (SVO) measure first. In a second step, we add the SECS scale and the preference

for a win by Trump in the 2020 presidential election. In the third step, we add psychological reactance, measured with the 11-item version of the Hong psychological reactance scale (Hong & Faedda, 1996). This is a potential predictor based on theory, but also has face validity based on items such as "Regulations trigger a sense of resistance in me".

We enter variables relating to game behavior only in the fourth and fifth step. In step four, we enter the number of H/no mask choices in the game. The variable "Risky-Choices" contains this value irrespective of condition. Step five adds predictors that allow to test for condition-specific prediction: The variable "mskRiskyChoices" codes the number of risky choices for participants in the pandemic framing and 0 for participants in the neutral framing. Similarly, "injRiskyChoices" codes the number of risky choices only for participants in the injunctive norm conditions, and "mskinjRiskyChoices" for participants in the condition with both pandemic framing and injunctive norms intervention. This results in four coefficients that can capture the relationship between risky choices and the criterion in each condition instead of a single parameter in Step four.

A5.3 Results for facial coverings

A5.3.1 Step 1

```
lmM1<-lm(behIntMasks~ CRT+riskTaking+angleSVO, data = modelFrame)
modM1<-Anova(lmM1, type="III")
print(modM1)

```

Adding the four game behavior variables significantly improves the model at the third step, but adding the three interaction coefficients in Step 5 also significantly improves the model at Step 4. The relationship between risky choices and the attitude towards facial masks is stronger with either pandemic framing or in the intervention condition (or in the pandemic framing with interventions. Note that in the latter condition all four coefficient values are added to determine the effect of risky choices (the sum is negative, even though it is smaller than the sum of the effects of framing and intervention). In all conditions, the number of H/no mask choices predicts a lower intention to wear actual masks during the pandemic.

A5.4 Results for physical distancing

A5.4.1 Step 1

```
lmD1<-lm(behIntDistancing~ CRT+riskTaking+angleSVO, data = modelFrame)
modD1<-Anova(lmD1, type="III")
print(modD1)
